## Objective of the cruise

The cruise L17-08 took place in the frame of the research project “Nordfriesland Süd – der geologisch/sedimentologische Aufbau und die Habitatverteilung im Übergangsbereich Watt – Schelf zwischen der Amrumbank und der Eiderrinne” (Nordfriesland South – the geological/sedimentological built up and habitat distribution in the transition zone between the tidal flats and the shelf zone between Amrum-Bank and Eider-Channel). The project is a cooperation between the Agency for Coastal Protection, National Park and Marine Conservation of Schleswig-Holstein (LKN), the State office for Agriculture, Environment and Rural Areas Schleswig-Holstein (LLUR) and Kiel University. The objectives are high resolution investigations of the sedimentary deposits of the subsurface, a stratigraphic classification of the mapped units, and the elaboration of a high resolution map of the sediment- and habitat distribution in this area.

The data sets will be used to fill gaps in the knowledge of sedimentological- and geological characteristics of this area. Another question is if the pre- Holocene subsurface still affects geomorphological forms and the morphological/sedimentological buildup of the present seafloor. This study also serves as a data pool to satisfy EU directives regarding marine habitats, seafloor characteristics and environmental impacts.

L17-08 was the first of a number of upcoming research cruises in the frame of this project. Here we focused on creating an overview of geological features and sedimentary structures of the seafloor and the upper subsurface down to about 10 m below the seafloor. We put special attention on the seaward extension of the base of tidal flats and the influence of tidal channels, shaping the geological structures and sediment distributions.

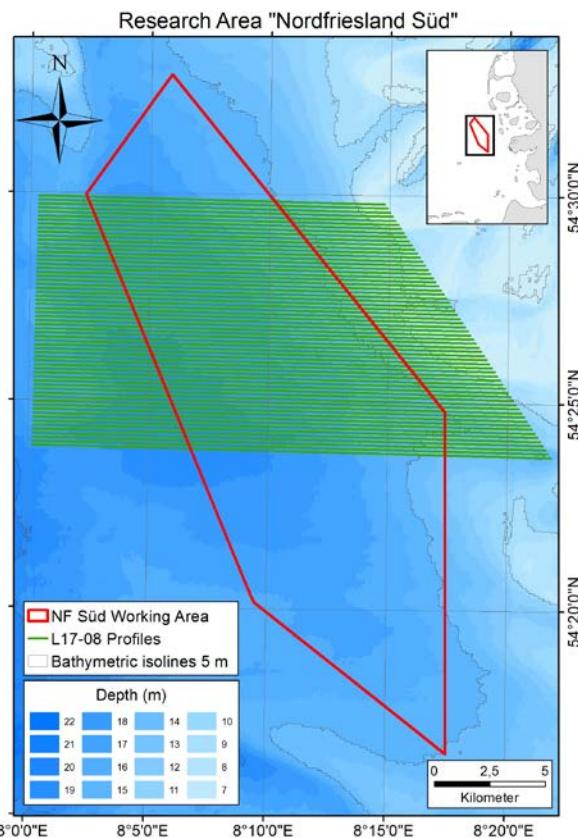

Fig. 1: Working area of "Nordfriesland Süd" (red lines). Tracks of hydroacoustic surveys (green lines). Bathymetry taken from [www.gpdn.de](http://www.gpdn.de).

## Abbreviations used in this report

Conductivity Temperature Depth probe	CTD
Institute of Geosciences	IfG
Multibeam Echosounder	MB
1624 – Side-Scan Sonar (towed)	SSS (1624)
C3D – Side-Scan Sonar (towed)	SSS (C3D)
Innomar Subbottom Profiler (hull mounted)	SES
Underwater Video	UWV
LKN	Landesbetrieb für Küstenschutz, National-Park und Meeresschutz Schleswig-Holstein
LLUR	Landesamt für Landwirtschaft, Umwelt und ländliche Räume Schleswig-Holstein

## Scientific Crew

Name	Function	Institute	Time on board
<b>Dr. Klaus Schwarzer</b>	Chief scientist	IfG, Kiel University	From 16.05.2017
<b>Dr. Peter Richter</b>	Scientist	IfG, Kiel University	Until 16.05.2017
<b>Dr. Daniel Unverricht</b>	Scientist	IfG, Kiel University	Complete
<b>M.Sc. Tim Willems</b>	Scientist	IfG, Kiel University	Complete

## Cruise Narrative

### **Mo. 15.05.2017**

Weather: E, 1 – 2, sunny  
09:00 Departure, transit through Kiel Canal, heading for working area, transit to Cuxhaven  
20:00 Arrival in Cuxhaven port

### **Tu. 16.05.2017**

Weather: S, 2 – 3, rainy  
06:00 Departure, transit to southern part of working area  
11:20 CTD-profile  
11:30 Deployment of devices (SSS, SES, MB), start hydroacoustic measurements  
17:15 End of hydroacoustic measurements, SSS, SES out of water, transit to Büsum, Change of crew members (Peter Richter leaves, Klaus Schwarzer arrives)

### **We. 17.05.2017**

Weather: 0, cloudy  
7:30 Departure, transit to northern part of working area  
12:00 CTD-profile  
12:35 Deployment of devices (SSS, SES, MB)  
12:50 – 00:00 Hydroacoustic measurements

### **Th. 18.05.2017**

Weather: WSW, 4 – 5, cloudy  
00:00 – 24:00 Hydroacoustic measurements

### **Fr. 19.05.2017**

Weather: 0, foggy  
00:00 – 15:30 Hydroacoustic measurements  
15:30 End of hydroacoustic measurements, SSS, SES out of water, transit to Büsum  
20:00 Arrival at Büsum harbor

### **Sa. 20.05.2017**

Weather: W, 3 – 4, cloudy, later sunny  
07:30 Departure, transit to northern part of working area  
13:30 Deployment of devices (SSS, SES, MB)  
13:40 – 00:00 Hydroacoustic measurements

### **Su. 21.05.2017**

Weather: W, 1 – 2, sunny  
00:00 – 24:00 Hydroacoustic measurements

### **Mo. 22.05.2017**

Weather: 0, sunny  
00:00 – 24:00 Hydroacoustic measurements

### **Tu. 23.05.2017**

Weather: 0, sunny, changing to WNW, 5 – 7  
00:00 – 11:00 Hydroacoustic measurements  
11:15 – 11:45 CTD, UWV  
12:00 Hydroacoustic measurements  
16:00 End of hydroacoustic measurements due to bad weather conditions  
SSS, SES out of water, transit to Helgoland harbor  
17:40 Arrival in Helgoland harbor

### **We. 24.05.2017**

Weather: WNW, 3 -4, sunny & cloudy  
07:30 Transit to working area  
10:30 – 17:15 Grab sampling  
18:00 Deployment of devices (SSS,, SES, MB)  
18:15 – 24:00 Hydroacoustic measurements

### **Th. 25.05.2017**

00:00 – 8:30 End hydroacoustic measurements  
8:45 SSS, SES & MB out of water  
9:00 – 16:40 Grab sampling  
16:50 Heading to Büsum  
21:00 Arrival in Büsum harbor

## **Methods**

Two Sidescan Sonar systems were used to collect high resolution hydroacoustic data to create maps of the seafloor sediment backscatter characteristics and sediment distribution patterns. The images are a reflection of the acoustic energy that is backscattered from the seafloor and is displayed in different levels of grey (Blondel et al., 1997). SSS devices were towed behind the vessel with a speed of 4.5 to 5 knots. The range was 100 m to each side, with an overlapping of each swath with the neighboring swath of 20 m (line spacing between the profiles: 0,1 nautical mile (nm)).

The SSS Teledyne Benthos C3D was used from 16. – 19. May. It runs with a frequency of 200 kHz. Due to negative influences of the SES subbottom profiler to the data quality, the SSS Teledyne Benthos SIS - 1624 (see Fig. 2 a) was replacing the C3D from May 20<sup>th</sup>. The dual frequency Benthos 1624 works with a 100 kHz and 400 kHz simultaneously. The track lines of all hydroacoustic profiles are shown in Fig. 1 and Tab. 1.

Multibeam surveys were performed with the shipboard SeaBeam 1185 (L3-Communications, ELAC Nautik GmbH), operating with a frequency of 180 kHz. Bathymetric and backscatter data can be collected simultaneously with an opening angle of 153.5° resulting in a swath of about 6 – 7 times of the water depth. The data was acquired and recorded using the software Hydrostar (L3-Communications, ELAC Nautik GmbH).

The Parametric sub-bottom profiler Innomar SES-2000 compact was used for collecting data of the built up of the subsurface down to about 15 m below the seafloor. The starboard-

mounted SES works with two different frequencies that are transmitted simultaneously at high sound pressures. The frequency overlap generates new frequencies which are used to penetrate the seafloor (for more details see (Innomar Technologie, 2009). The system operates in chirp frequency mode.

At the beginning of each survey the devices for hydroacoustic measurements were calibrated for sound velocity using data from CTD profiles of the water-column.

A Van- Veen- Grab Sampler (fig. 2 b) was used to collect sediment samples from the seafloor. Every grab sample was described, photographed and sampled (see Tab. 2). In addition, ground truthing was performed at one profile (see Tab. 4) with a Mariscope Underwater Video System while drifting with the current velocity of about 0.5 - 1 kn.

## Preliminary Scientific Results

The SSS mosaic resulting from 62 profiles (Fig. 3) covers an area of about 116 km<sup>2</sup>. The surveyed area is generally characterized by a high amount of zones of low backscatter values (bright colors). Highest backscatter values (dark colors) can be seen in the north and in the south of the eastern part of the SSS mosaic. Especially the western part of the mapped area reveals lower backscatter values. Further, the western area is also slightly elevated (1 – 2 m) in comparison to the middle- part. This elevation is associated with the extension of the geomorphological structure of Amrumbank extending towards south. The transition from the brighter area to the slightly darker middle-part of the SSS recordings is marked by linear parallel backscatter variations. These variations can be interpreted as ripple structures (Blondel, 2009). The ripple valleys seem to contain coarse grained sediment, which is displayed by higher backscatter values (Fig. 4). The ripples show a height of about 0.5 m with wavelength from five to ten meters.

### Sidescan Mosaic of RV cruise L17-08

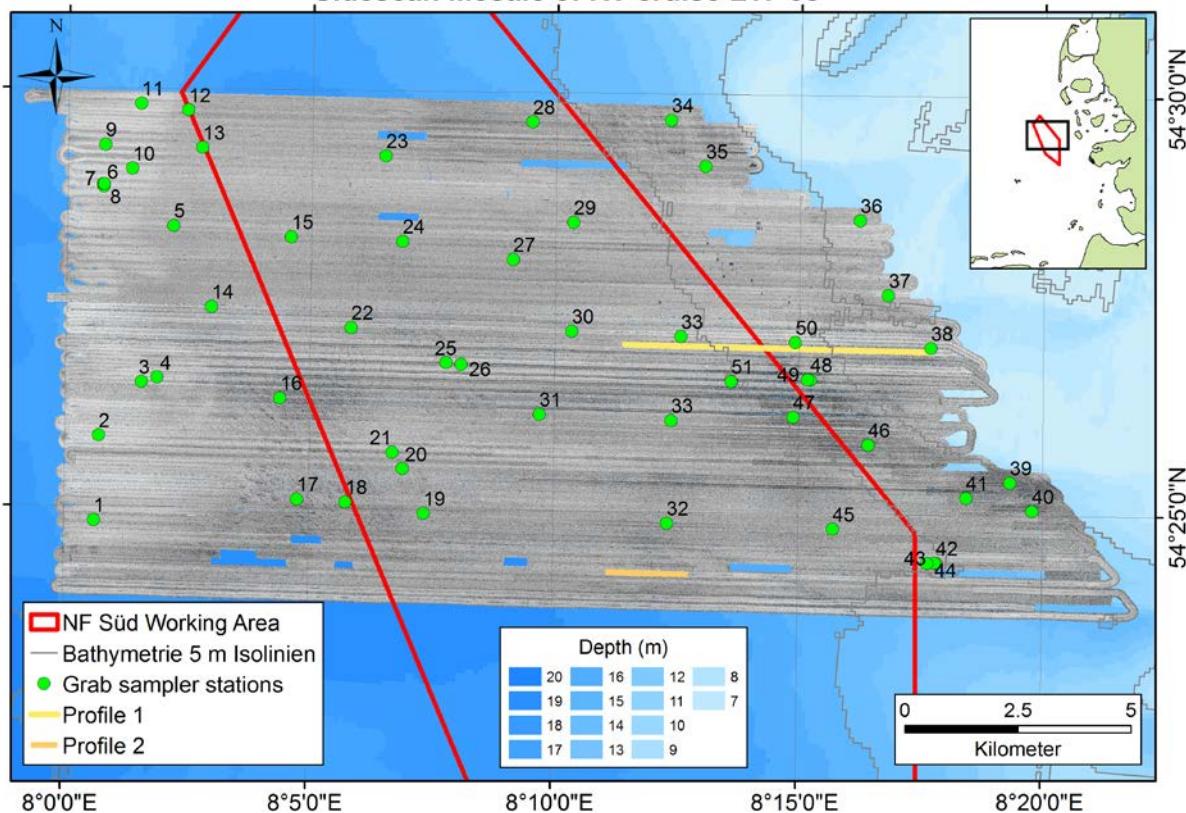

Fig. 3: Sidescan mosaic (light colors represent low backscatter while dark colors represent high backscatter) and grab sampling stations (green dots) of the cruise L17-08.

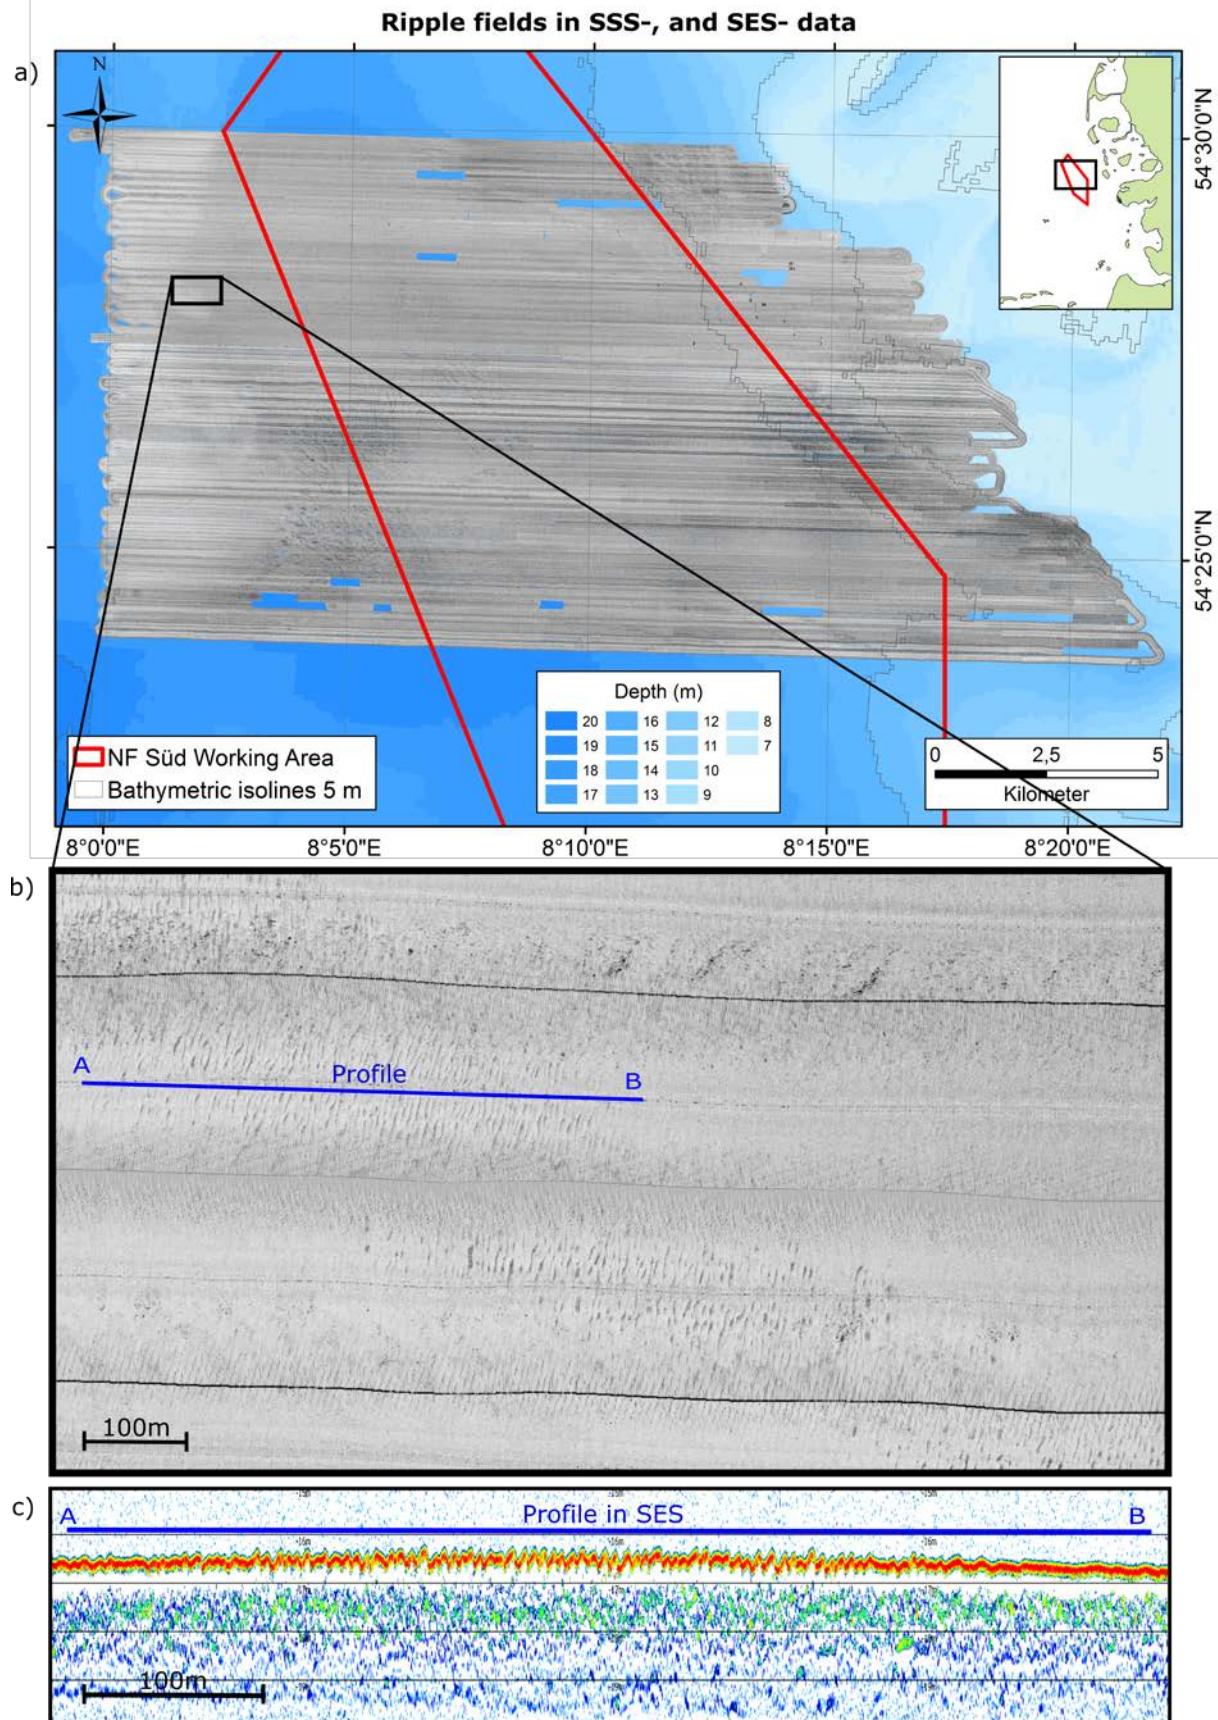

Fig. 4: a) SSS- mosaic overview; b) an area of ripples marks the border between brighter (left) and darker (right) backscatter in SSS recordings; c) Ripples can clearly be detected as well in SES profiles.

SSS recordings revealed occasional positions with higher backscatter intensities and patchy appearance on varying scales - ten to hundreds of meters. These surface reflections may be associated either with bioactivity, e.g. the tube worm *Lanice conchilega* (Heinrich et al., 2017; Degraer et al., 2008), or with morphodynamic structures, e.g. sorted bedforms (Murray et al., 2004; Diesing et al., 2006). In addition, N – S and NW – SE trending fishing traces can be seen in the SW- and the NE of the investigated area. Those are marked by two parallel running stripes of backscatter variations.

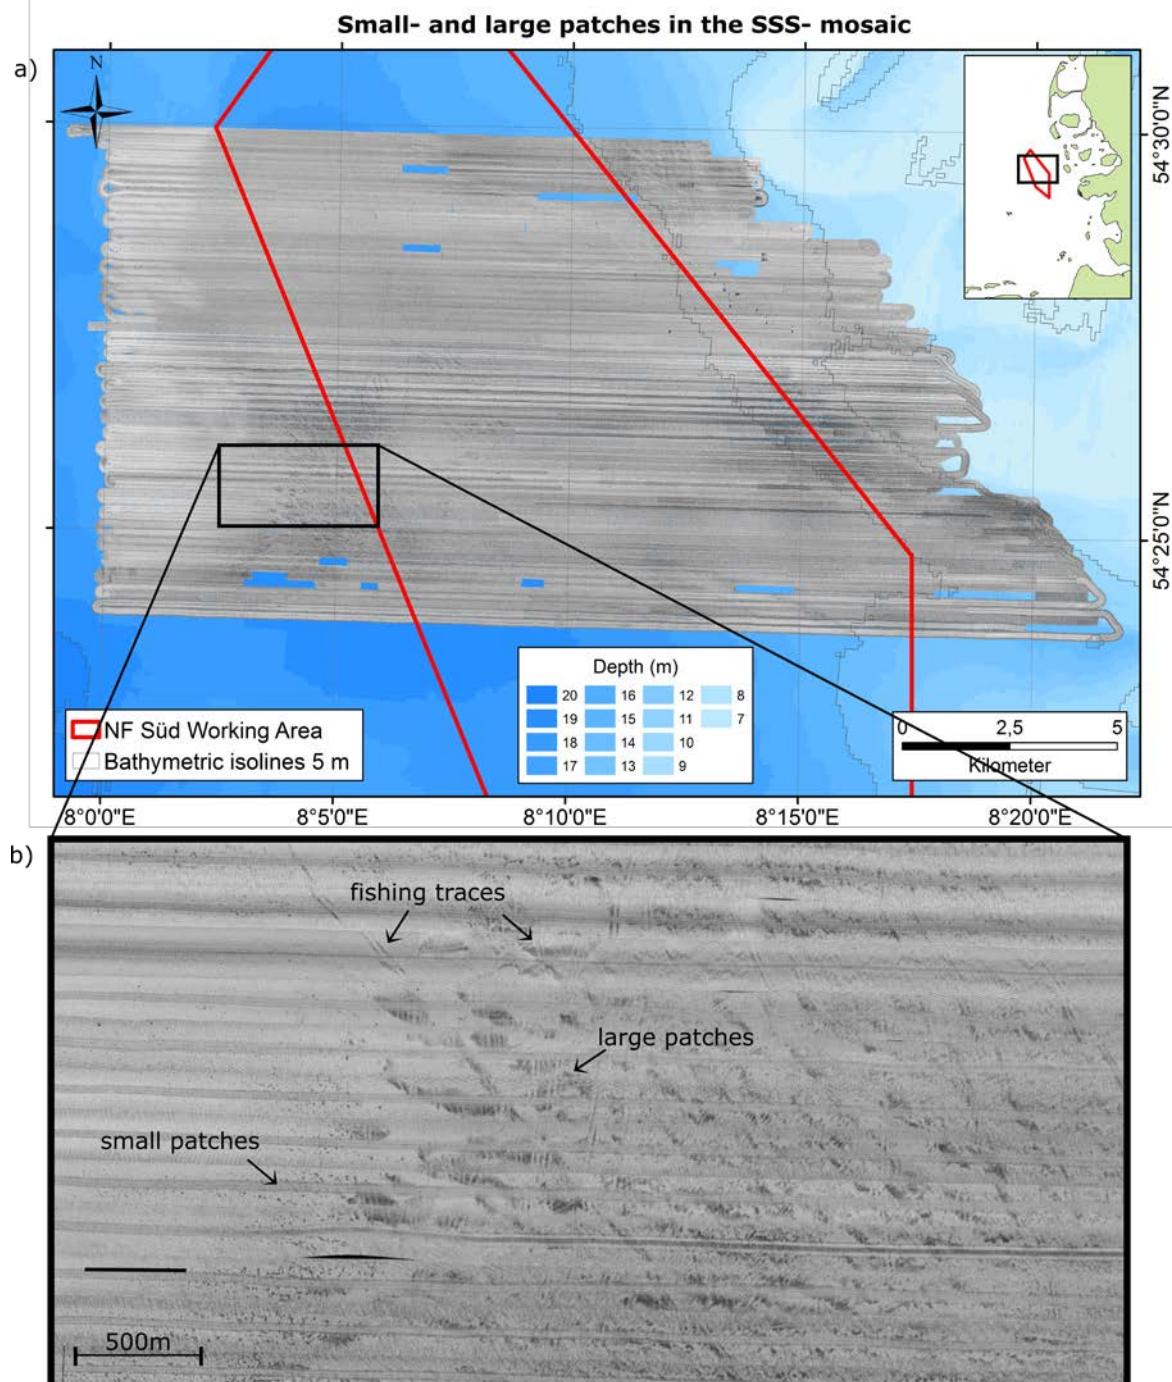

Fig. 5: a) SSS- mosaic overview; b) Zoom into SSS- mosaic with visible fishing traces, small-, and larger patches with high backscatter compared to the surrounding area;

Based on the SSS-mosaic, grab sampling was carried out on 51 stations (see Tab. 2). The Sediment probes were described aboard, sieved and classified according to Folk & Ward (1957).

The central part of the recorded area is dominated by fine sand containing small amounts of mud. Most samples were weakly bioturbated. Small populations of juvenile *Lanice conchilega* tubeworms were also found in the majority of samples (Fig. 6, pictures NFS250517-05 and NFS250517-27. Further, *Ensis* razors clams and sea urchins were found occasionally.

The slightly elevated and brighter part of the SSS- mosaic in the west area contains middle-to fine sand, as seen in the sample NFS250517-09.(Fig. 6). No bioturbation was identified, but sometimes living Macoma shells was found.

The sediment in the patchy areas is characterized by grain sizes from mud to fine sand. It is often strongly bioturbated and contains *Nereis*, *Macoa*, *Ensis* and sea urchins. The picture of sample number NFS250517-18 shows an example for this area.

A lot of biological activity also characterizes the south-eastern darker part in the SSS- mosaic. The muddy fine sand is often strongly bioturbated and contains more than 1 % of shell fragments, faecal pellets, living crabs and brittle stars on the surface as well as worms inside the sediment (see picture NFS250517-40, which also contains a lot of juvenile *Lanice conchilega* and sample number NFS250517-46).

Fig. 7 shows two SES – transects: Profile 1: line 20170520\_4\_b; profile 2: line 20170523\_5b, extending from west to east in water depths of about 11 – 18 m. Seismic reflectors are illuminated by different colors, depending on the intensity of acoustic energy reflection (red: highest intensity; blue; lowest intensity). The profile contains five examples of the most abundant seismological sediment structures (Posamentier et al., 1988; Van Wagoner et al., 1988), marked by number 1 to 5.

Six seismic units could be differentiated (Fig. 7). The seismic facies are classified as follows:

- 1) Presumably pre- Holocene Sediments marked by a strong reflector at the top, leading to very weak and diffuse-, or no internal reflections. It forms the base of acoustic penetration and can be seen as the border between Pleistocene and Holocene deposits (Zeiler et al., 2000; Figge, 1980)
- 2) Downlap structure 1; predominantly parallel- layered sediments with differing dipping angles, which unconformably fill morphological structures of the underlying sediment. The dipping angle of the sediment layers decreases towards the western deeper parts. The thickness of the sediment body exceeds the maximum penetration depth of about 7 m in places where layer 1 is not visible. The top is cut unconformably by the seafloor in the western part and layer 3 in the eastern part.
- 3) Downlap structure 2; the seismic facies is marked by clearly distinct sedimentary layers, that unconformably overly “Downlap structure 1”. The dipping angle of the layers varies, with low angles in the western part and higher angles in the eastern part. The top of the structure is marked by a truncation, cutting the comprising layers in about 16 m depth.

- 4) Offlap structure; the continuous and parallel reflector slightly dips towards west at a constant angle. This seismic unit unconformably overlies unit 3 and is cut truncated at the top (surface)
- 5) Surface; the surface represents the strongest reflector.
- 6) Incised valley; a valley eroded into the underlying structure (1) and was refilled in clearly laminated fashion (Dalrymple, 2006).
- 7) Local elevation of a deeper structure. This structure has a marked top- reflector and seems to break through layer 1 from deeper part.

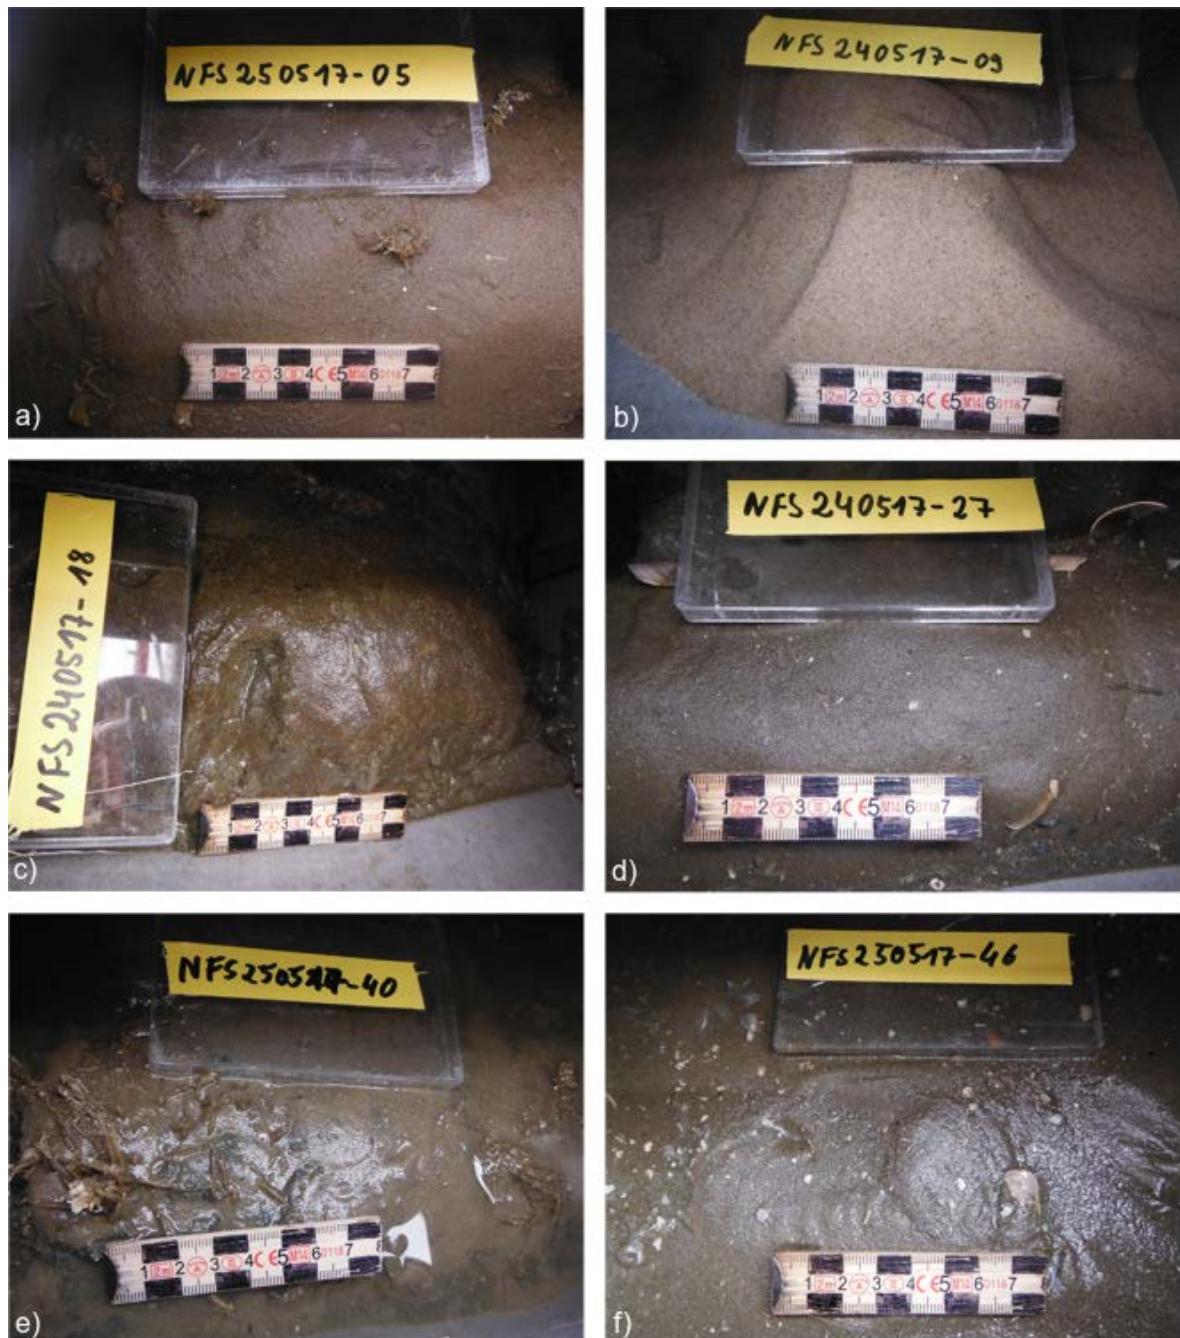

Fig. 6: Van Veen Grab Sampler probes: a) NFS250517-05; b) NFS240517-09; c) NFS240517-18; d) NFS240517-27; e) NFS250517-40; f) NFS250517-46; Sampling locations are shown in Fig. 1.

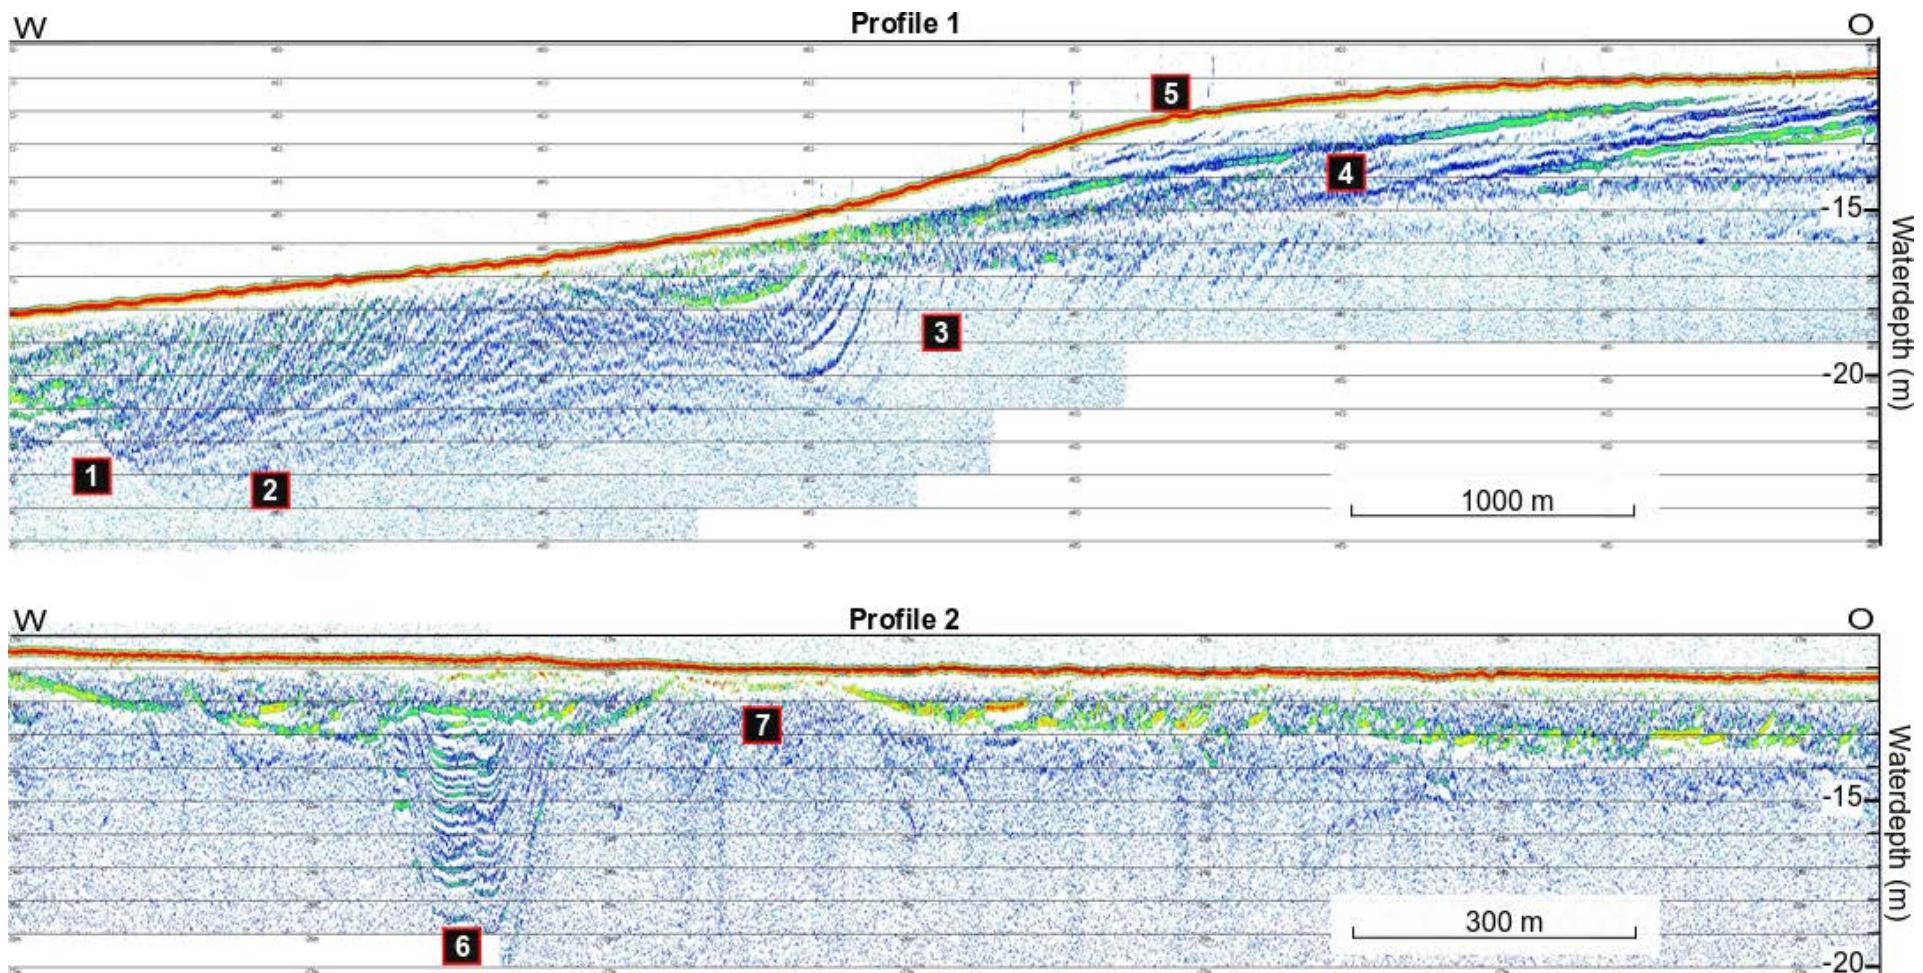

Fig. 7: Two SES Profiles representing some common seismological structures of the research area; profiles are shown in Fig1. a) Profile 1, b) Profile 2. Numbers represent different structures: 1) Pre- Holocene Sediments; 2) Downlap structure 1, 3) Downlap structure 2, 4) Offlap structure, 5) Surface, 6) Incised valley, 7) Local elevation of a deeper structure.
