## Code Description

The following is the R code for preparing and plotting the dot map figures in the manuscript. The scripts are based on the 'paleofire' and 'GCD' R packages, which were developed in conjunction with this research and are available from the Comprehensive R Archive Network (CRAN). Briefly, the first script sets up options for the gridding procedure, including the extent and resolution of the grid, target ages for analysis, binning and analysis half-window widths, the number of bootstraps to include in confidence calculations, and several graphical parameters for presenting the final plots. The script then selects data from all sites in the GCD database, processes them according to the methodology described in the main text, and saves the results for later use. The second script starts from this saved output, sets various graphical parameters, and then produces gridded dot maps of mean CHAR z-scores, number of sites contributing to each dot, and the number of dots contributed to by each site (e.g., figures 5, 6, and 7 in the main text). An option allows the plots to be displayed in the R window, or saved to PDF.
