## Analytical procedures

## Dissolved organic carbon

The calibration for DOC was made with the TOC standard solution ( $1000 \mathrm{mg} \mathrm{L}^{-1}$ from MerckCertipur® ref. 109017) over the measurement range of $0-600 \mu \mathrm{MC}$, and Deep Sea Water reference (Batch $10-2010$ Lot \#05-10) from Hansell laboratory, University of Miami, Florida. Every measurement day, ultrapure (Milli-Q) water was used to determine the instrument blank, which was accepted for values $<1 \mu \mathrm{~mol} \mathrm{C} \mathrm{L}{ }^{-1}$. DOC concentration was determined in each sample from 5 to 8 injections. The precision was $<4 \%$ estimated as the standard deviation of replicate measurements divided by the mean.

## Dissolved hydrolysable amino acids

For dissolved hydrolysable amino acids (DHAA), 1 mL of sample and 1 mL of $30 \%$ hydrochloric acid $(\mathrm{HCl})$ (Merck, suprapure) were hydrolyzed in sealed ampoules at $100^{\circ} \mathrm{C}$ for 20 h . The hydrolysate was dried in a microwave under nitrogen atmosphere and was washed twice with 0.5 mL of ultrapure water to remove the HCl . Finally the samples were re-dissolved in 1 mL ultrapure water. Amino acids were separated by HPLC (1260, Agilent) equipped with a C18 column (Phenomenex Kinetex, $2.6 \mu \mathrm{~m}, 150 \mathrm{x} 4.6 \mathrm{~mm}$ ) after in-line derivatization ( 2 min ) with ophthaldialdehyde and mercaptoethanol. For solvent A 0.1 M sodiumdihydrogenphosphate was adjusted to pH 7 with sodium hydroxide $(\mathrm{NaOH})$ and premixed with acetonitrile ( $19: 1 \mathrm{v} / \mathrm{v}$ ). Solvent B was acetonitrile. A linear gradient was run starting from $6 \%$ solvent B to $27 \%$ solvent B in 40 $\min$ at a flow rate of $0.8 \mathrm{~mL} / \mathrm{min}$. The following standard amino acids were used: aspartic acid (AsX), glutamic acid (GlX), serine (Ser), arginine (Arg), glycine (Gly), threonine (Thr), alanine (Ala), tyrosine (Tyr), valine (Val), phenylalanine (Phe), isoleucine (Ileu), leucine (Leu), $\gamma$ - amino butyric acid (GABA). $\alpha$ - amino butyric acid was used as an internal standard to account for losses during handling. Standards were run in the beginning as well as after each $5^{\text {th }}$ sample. The detection limit for individual amino acids was 2 nmol monomer $\mathrm{L}^{-1}$. The precision was $<5 \%$, estimated as the standard deviation of replicate measurements divided by the mean.

## Dissolved uronic acids

Samples for dissolved uronic acids (DURA) were desalinated by membrane dialysis (1 kDa MWCO, Spectra Por) for 5 h at $6^{\circ} \mathrm{C}$, hydrolyzed for 20 h at $100^{\circ} \mathrm{C}$ with 0.8 M HCl final concentration and neutralized through acid evaporation $\left(\mathrm{N}_{2}, 5 \mathrm{~h}, 50^{\circ} \mathrm{C}\right)$. Ultrapure water was added to the dry residue and two replicate samples were analyzed by Ion Chromatography (Dionex ICS 3000). The acidic sugars: galacturonic acid ( $2.8 \mu \mathrm{M}$, Gal-URA), gluconic acid ( $5.1 \mu \mathrm{M}$, Glu-Ac), glucuronic acid ( $3.0 \mu \mathrm{M}$, Glc-URA) and muramic acid ( $1.9 \mu \mathrm{M}$, Mur-Ac) were used as standards in a mixed solution. Regular calibration was performed by injecting $12.5 \mu \mathrm{l}, 15.0 \mu \mathrm{l}, 17.5 \mu \mathrm{l}$ and $20 \mu \mathrm{l}$ of mixed standard solution. Linearity of the calibration curves of individual sugar standards was verified in the concentration range $10 \mathrm{nM}-10 \mu \mathrm{M}$. Therefore, the standard mixture was diluted 10 , 20, 50, and 100 fold with Milli-Q water. Injection volume for samples and for the blank was 17.5 $\mu$. The detection limit was 10 nM for each sugar with a precision of $13 \%$ estimated as the standard deviation of replicate measurements divided by the mean. Milli-Q water was used as blank to account for potential contamination during sample handling. Blanks were treated and analyzed in the same way as the samples. Blank concentration was subtracted from sample concentration if above the detection limit.

## Marine gel particles: TEP and CSP

The size frequency distribution of marine gel particles was determined according to their ESD, described with a power function of the type:

$$
d N / d\left(d_{p}\right)=k_{p}^{\delta}
$$

where $d N$ is the number of particles per unit volume in the size range $d_{p}$ to $\left[d_{p}+d\left(d_{p}\right)\right], k$ is a constant which depends on the concentrations of particles, and $\delta$ is the spectral slope $(\delta<0)$ describing the size distribution. A less negative $\delta$ implies an increase in the fraction of larger marine gels. $k$ and $\delta$ were both derived from regressions of $\log \left[d N / d\left(d_{p}\right)\right]$ versus $\log \left[d_{p}\right]^{1-3}$. The volume concentration of TEP and CSP refers to the mean volume of the particles $>0.4 \mu \mathrm{~m}$ which was the membrane pore size cutoff; changes in this parameter indicate particles dynamics such as aggregation/disaggregation processes. Since TEP are considered as fractal aggregates, the volume and the carbon content of these marine gel particles are assumed to be proportional to $r^{D}$, with $r$ being the equivalent spherical radius $(\mu \mathrm{m})$ and $D$ the fractal scaling dimension associated with the size-distribution of marine gels ${ }^{1,2,4}$. TEP carbon content (TEP-C micro , expressed in $\mu \mathrm{M}$ ), was determined from marine gel size spectra according to Mari ${ }^{5}$ and Engel ${ }^{4}$ :

TEP-C micro $\left[\mu \mathrm{g} \mathrm{L}^{-1}\right]=0.25 \times 10^{-6} r^{D}$
with $D=2.55$

## Supplementary Figures

Figure S1a-d. Total area and abundance of gel particles in the SML. Total area $\left[\mathrm{mm}^{2} \mathrm{~L}^{-1}\right]$ : (a) proteinaceous CSP, (b) polysaccharidic TEP. Abundance of submicron gel particles: (c) proteinaceous CSP, (d) polysaccharidic TEP. The horizontal lines of the boxes represent $25 \%, 50 \%$ (median) and $75 \%$ percentiles (from bottom to top). In the boxes, crosses represent the mean. Whiskers represent minimum and maximum values, and circles are outliers.

Figure S2. Slope ( $\delta$ ) of gel particles (TEP, CSP) in freshwater melt ponds, open melt ponds and open sea. A less negative slope implies a higher fraction of larger gel particles among the gel particles pool. The vertical lines of the boxes represent $25 \%, 50 \%$ (median) and $75 \%$ percentiles (from left to right). In the boxes, crosses represent the mean. Whiskers represent minimum and maximum values, and circles are outliers.
