1 Cruise Summary

1.1 Summary in English

This multidisciplinary cruise extended a long-term data series on ecosystem composition and functioning of the deeper basins of the Baltic Sea that has been collected in similar form since 1987. The key characteristic of the cruise was the integration of oceanographic and biological information to enhance understanding of environmental, plankton dynamics and fish population fluctuations, and ultimately, evolutionary processes in this system. The spatial focus lay on the Bornholm Basin as most important spawning area of Baltic cod, but also included the Western Baltic Sea, Arkona and Gotland Basin, Gdansk Deep, and Stolpe Trench. All objectives of the cruise were achieved, benefiting from perfect weather conditions and flawless performance of all instruments and gear.

The detailed hydrological survey (oxygen, salinity, temperature) of the entire cruise area showed higher water temperatures and an improvement of the oxygen situation in deep water layers compared to the same time period in 2018. Plankton surveys (zoo- and ichthyoplankton including gelatinous plankton, with the goal to determine the composition and the abundance and vertical and horizontal distribution of species, and to take samples for later measurements of nutritional condition) showed a much higher abundance of jellyfish larvae (“ephyrae”) and small adults than in 2018. Regarding fish larvae, sprat and flounder larvae were abundant but very few cod larvae were present throughout the cruise area, both of which was consistent with the situation in previous years. Pelagic fishery hauls were carried out as planned to determine stock structure and to obtain a range of different samples (gonads, livers, stomachs, tissue samples, otoliths) for cod, whiting, sprat and herring as well as different flatfish species, and are the foundation for a range of different individual-level genetic and ecological analyses to be carried out in the laboratory on land. The abundance and distribution of fishes in the cruise area was also assessed continuously over the duration of the cruise with hydroacoustic methods. As in previous years, cod, herring, sprat and flounder dominated catches. Catches of cod increased compared to 2018, but the absence of large cod individuals in particular in Bornholm Basin was consistent with observations in previous years. Finally, the work for all additional collaborative projects, including in-depth sampling of planktonic food webs for dietary tracer work, sampling and experimental work of photosynthesis and respiration rates of different phytoplankton fractions and finally, pelagic fish stomach and plankton sampling for eDNA assessments was carried out successfully.

The resulting data- and sample sets support ongoing projects in the Research Unit Marine Evolutionary Ecology at GEOMAR, as well as the EU Horizon 2020 project GoJelly and several international collaborations.

1.2 Deutsche Zusammenfassung

Diese multidisziplinäre Ausfahrt erweitert eine seit 1987 in ähnlicher Form laufende Lanzeitdatenreihe zur Ökosystemzusammensetzung und -funktion der Ostsee mit Schwerpunkt auf die tieferen Becken. Alle Ziele der Ausfahrt wurden erreicht, begünstigt von perfekten Wetterbedingungen und fehlerfreien Performance aller Geräte und Instrumente. Ein Schlüsselmerkmal der Ausfahrt war die Integration ozeanografischer und biologischer Daten, um das Verständnis von Schwankungen in Umweltparametern, Planktongemeinschaften und Fischpopulationen und letztendlich der Evolutionsprozesse in diesem System zu verbessern. Die daraus resultierenden Daten- und Probensätze unterstützen laufende Projekte in der Abteilung Marine Evolutionsökologie am GEOMAR sowie das EU-Horizont 2020-Projekt GoJelly und mehrere internationale Kooperationen. Der räumliche Schwerpunkt lag auf dem Bornholmbecken als wichtigstem Laichgebiet des Ostseedorsches, schloss aber auch die westliche Ostsee, das Arkona- und Gotland-Becken, das Danziger Tief sowie die Stolper Rinne ein.

Die detaillierte hydrologische Untersuchung (Sauerstoff, Salzgehalt, Temperatur) des gesamten Fahrtgebiets ergab höhere Wassertemperaturen und eine Verbesserung der Sauerstoffsituation in tiefen Wasserschichten im Vergleich zum gleichen Vorjahreszeitraum. Planktonuntersuchungen (Zoo- und Ichthyoplankton einschließlich gelatinösem Plankton) mit dem Ziel, die Zusammensetzung und Häufigkeit sowie die vertikale und horizontale Verteilung der Arten zu bestimmen und Proben für spätere Messungen des Ernährungszustands zu entnehmen, zeigten ein deutlich höheres Vorkommen von Quallen-Ephyren als 2018 und ein weit verbreitetes Vorkommen von Sprotten- und Flunderlarven. Die Anzahl der Dorschlarven war wie in den Vorjahren sehr gering. Pelagische Fichereihols zur Bestimmung der Bestandsstruktur, des Reifegrads und der Fruchtbarkeit, sowie der Mageninhalte von Dorsch, Sprotte und Hering, sowie die Entnahme von Organen, Gewebe- und Otolithenproben für genetische und ökologische Analysen des Dorsches wurden wie geplant durchgeführt. Fischbestände wurden außerdem mit Hilfe von Hydroakustikaufnahmen im gesamten Fahrtgebiet erfasst. Wie in den Vorjahren dominierten Dorsch, Hering, Sprotte und Flunder die Fänge. Die Dorschfänge nahmen im Vergleich zu 2018 zu, auffällig war dabei wie schon in den Vorjahren die Abwesenheit großer Dorschindividuen insbesondere im Bornholmbecken. Die eingehende Analyse der resultierenden Proben- und Datensätze steht noch aus.

Zu guter Letzt konnten alle im Rahmen von externen Kollaborationen geplanten Arbeiten, einschließlich der Detailbeprobung planktonischer Nahrungsnetze für die Untersuchung mit Nahrungsnetztracern, der Probenahme und anschließenden experimentellen Arbeiten an Bord zu Photosynthese und Respiration verschiedener Phytoplanktonfraktionen, und der Beprobung der Mägen der pelagischen Fischarten Hering und Sprotte sowie Planktongemeinschaften für eDNA-Analysen, erfolgreich durchgeführt werden.

3 Research Program (including Work Area, Aims and Agenda)

The Baltic Sea is comparatively speaking species poor, yet it provides enormous ecosystem services to the Baltic nations. At the same time, it is one of the systems most affected by the combination of global (including climate) and local anthropogenic changes, and has undergone strong hydrographic and biological shifts in the past decades.

Cruise AL521 extended a 32-year integrative long-term data series of the deep basins of the central Baltic Sea collected since 1987 by the GEOMAR Helmholtz Centre for Ocean Research and its predecessors IFM-GEOMAR Kiel and IFM Kiel. The specific spatial focus was on the Bornholm Basin as most important spawning area of Baltic cod, but also included the western Baltic Sea, Arkona and Gotland Basin and Gdansk Deep (Figure 3.1), thus covering ICES subdivisions (SD) 22, 24, 25, 26 and 28 (Figure 3.2).

The key characteristic of the cruises contributing to this time series is the integration of oceanographic and biological information, to allow the analysis of Baltic pelagic food webs and (fish) species across the environmental gradients of the Baltic Sea, and under changing environmental conditions and human exploitation patterns over time. In this context, the datasets and samples obtained during cruise AL521 are essential for a number of projects, including the large-scale international project EU Horizon 2020 GoJelly and collaborations with the Technical University of Denmark, National Institute of Aquatic Resources (DTU Aqua), Stockholm University, and the University of Hamburg.

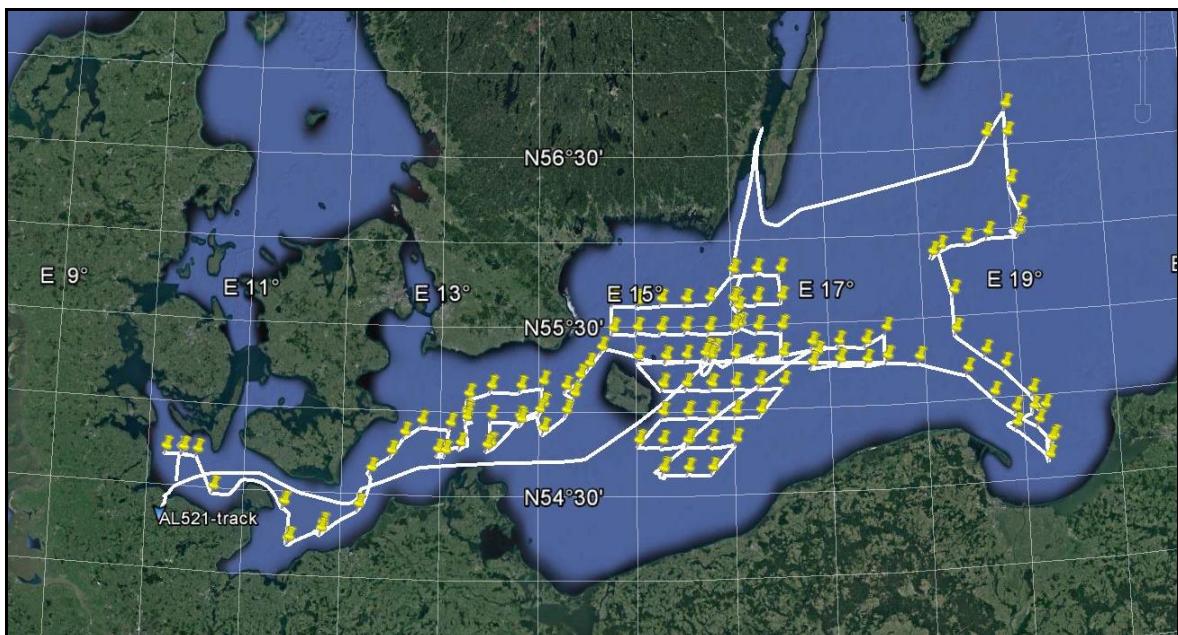

Figure 3.1 Cruise track of AL521, with stations indicated by yellow pins (Map produced in Google Earth).

Figure 3.2 ICES subdivisions in the cruise area (Source: ICES). ICES SD22 corresponds to Kiel Bight = KB, SD24 to Arkona Basin = AB, SD25 to Bornholm Basin = BB and Stolpe Trench = SR, SD26 to Gdansk Deep = GD and Southern Gotland Basin (GB).

Specific investigations during AL521 included (1) a detailed hydrographic survey (oxygen, salinity, temperature) (109 stations along the cruise track, see Figure 3.1), (2) zoo- and ichthyoplankton surveys to determine the composition, abundance, vertical and horizontal distribution and nutritional status of species as well as patterns of plankton phenology (same 109 stations, Figure 3.1), (3) whole food web sampling including nutrients, seston, phyto-, zoo- (including jellyfish) and ichthyoplankton (4 stations), and (4) pelagic fishery hauls (25 stations). The latter served firstly to determine size distributions, maturity status, and length – weight relationships of the three dominant fish species in the pelagic system of the Baltic, cod (*Gadus morhua*), herring (*Clupea harengus*) and sprat (*Sprattus sprattus*) as well as flatfishes including flounder (*Platichthys flesus*). Secondly, various samples for more detailed analyses back on land were obtained, including cod gonads, livers and otoliths, herring and sprat stomachs and whole samples for dietary analyses, and tissue samples of cod, flounder, whiting, plaice and other species for genetic and stable isotope analysis. In addition, hydroacoustic data were collected continuously along the cruise track for later analysis of fish abundance and distribution. Finally, additional work in the context of collaborations with external groups were (5) sampling and experimental work of photosynthesis and respiration rates of different phytoplankton fractions and (6) pelagic fish stomach and plankton sampling for eDNA assessments.

4 Narrative of the Cruise

RV ALKOR was loaded on the days prior to the onset of the cruise. ALKOR then departed from the GEOMAR Westshore pier on April 16 2019 at 08:00 am (all times board time) and headed to the first research area in Kiel Bight (SD22). In the following, all work laid out in the original cruise program was accomplished as planned, benefiting from perfect working conditions on board without any equipment problems. Weather over the duration of the cruise was calm, warm and mostly sunny, in an unusual departure from weather patterns experienced during April cruises in the same working area in previous years.

Over the course of the cruise, pelagic fishery hauls, zooplankton hauls with Bongo/IKS-80 nets, water sampler, and CTD hauls were carried out following a large-scale spatial sampling design covering Kiel Bight (SD22) on April 16, Mecklenburg Bight (SD22) on April 17, Arkona Basin (SD24) on April 18-19, Bornholm Basin (SD25) on April 20 and again in more detail from April 25 to May 1, Stolpe Trench (SD25) on April 20, Gdansk Deep (SD26) on April 21-22, and Gotland Basin (SD26) on April 23 (Figure 3.1, 3.2). Hydroacoustic data obtained with four different echosounder frequencies (38, 70, 120 and 200 kHz) were continuously recorded over the duration of the cruise.

The scientific work was interrupted by a scheduled harbor stay in Kalmar, Sweden on April 23-25 to disembark two scientists and embark two replacements. The stay was extended by one day due to a passing low pressure system and strong winds in the cruise area on April 24.

In addition to the program above, the central deep station BB23 in Bornholm Basin was intensively sampled on two occasions, early in the cruise on April 20 (including CTD casts, zooplankton sampling with Bongo, Apstein and WP-2 nets, oxygen measurements of water samples obtained with the rosette water sampler with the Winkler method for the calibration of oxygen probe measurements, and phytoplankton sampling) and late in the cruise on April 30 – May 1 (same sampling as on April 18, followed by the detailed vertically and temporally resolved sampling of plankton communities by four towed Multinet MAXI and four vertical Multinet MIDI hauls over a 24 hour period, covering the water column in 5 m and 10 m depth layers, respectively). Moreover, whole food web samples (nutrients, seston, phyto- and zooplankton including jellyfish and fish larvae) were obtained at 4 stations, using a combination of water sampler, Bongo, WP-2 and WP-3 hauls. Additional sampling was carried out throughout the cruise area for the special projects on phytoplankton communities (surface water samples at 16 stations) and on eDNA assessments of pelagic fish diets (7 stations). Table 4.1 provides a spatially resolved overview over all gear deployments during AL521.

Table 4.1 Overview of gear deployments during AL521. Mesh sizes of all nets are given in brackets. For location designations (combination of ICES SD and abbreviated name), see Figure 3.2.

5 Preliminary Results

5.1 Ichthyo– and zooplankton sampling

Bongo- and Babybongo hauls covered Kiel Bight (5 hauls), Mecklenburg Bight (4 hauls), Arkona Basin (24 hauls), and Bornholm Basin including the western part of Stolpe Trench (53 hauls) (Table 4.1). Larvae of sprat (*Sprattus sprattus*; n = 1027), flounder (*Platichthys flesus*; n = 677), sculpin (*Myoxocephalus scorpius*, n = 2), common seasnail (*Liparis liparis*; n = 67) and sandeel (*Ammodytes tobianus*; n = 1) were picked from the 500 µm bongo-samples and 300 µm Multinet samples and conserved at -80 °C for subsequent RNA/DNA, stable isotope and genetic analyses. A low number (n = 6) of cod (*Gadus morhua*) larvae was found. This compares to a complete lack of cod larvae in catches in 2018, but is generally consistent with low abundances observed on our spring cruises in previous years. It also fits the observation of a long-term, decadal scale shift in the reproductive period and the subsequent occurrence of cod larvae in the Bornholm Basin from spring to summer months.

All of the 500 µm Bongo und the 300 µm Multinet MAXI samples were also checked for the presence of gelatinous zooplankton. Ephyrae (larvae) and small adults of scyphozoan jellyfish (identified on board as *Cyanea capillata*, potentially low numbers of *Aurelia aurita*) were present in much higher abundances than in 2018 (n = 1550 vs. less than 10), whereas the invasive combjelly *Mnemiopsis leidyi* was present only in low numbers (n = 5). A possible explanation may lie in the much higher water temperatures in 2019 compared to the same period in 2018, and possible effects on the phenology of gelatinous zooplankton. Following these initial on board steps, all Bongo samples were conserved in formol, and are available for the determination of species composition and abundance of zoo- and ichthyoplankton.

Stations in the eastern part of Stolpe trench and in the Gdansk Deep and Southern Gotland Basin were sampled with IKS-80 nets instead of Bongo nets to ensure the compatibility

of data with a long-term IKS-80 sampling series maintained by the Latvian Fish Resources Agency (LATFRA; Andrei Makarcuks).

Repeated Multinet MAXI (300 µm, towed, sampling of the water column in 5 m layers) and MIDI (50 µm, vertical, sampling of the water column in 10 m layers) casts were done over a 24 hour period on April 30 – May 1 on the central deep Bornholm Basin station BB23 to assess diurnally resolved vertical distributions of ichthyo- and zooplankton. A notable pattern here was the different depth distribution of jellyfish (centered around the 50–55 m depth line, little diurnal vertical variation) and fish larvae (e.g., sprat: diurnal migration from depths around 20 m during the day to the surface at night) (Figure 5.1.1).

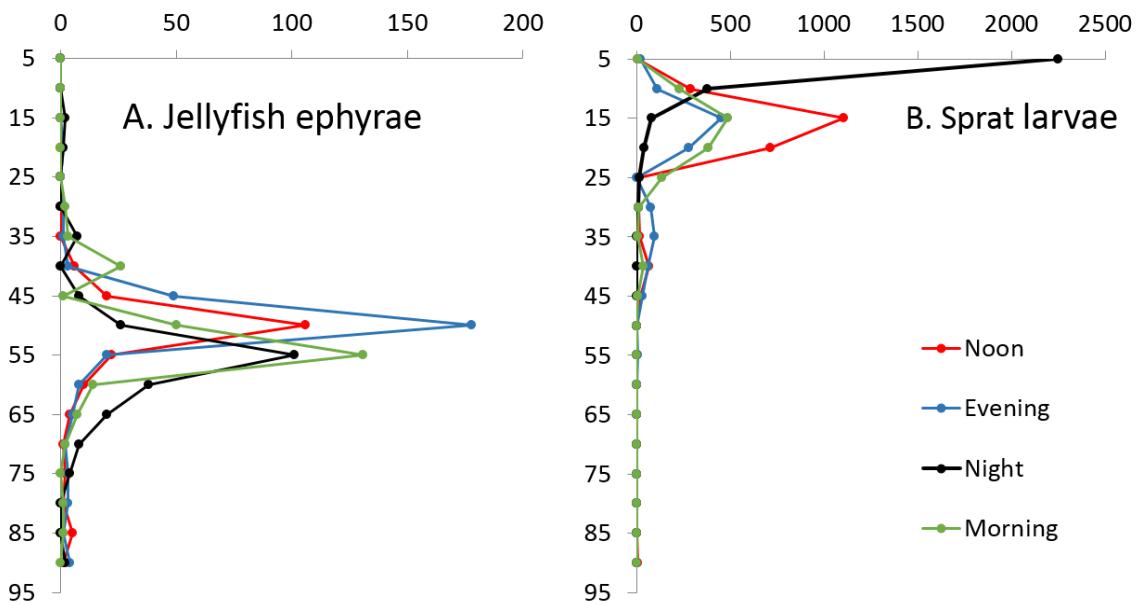

Figure 5.1.1 Depth distribution of A. jellyfish ephyrae (*Cyanea capillata*) and B. sprat (*Sprattus sprattus*) larvae observed on the central Bornholm Basin station BB23 over a 24 hour period on April 30 – May 1 2019.

5.2 Fishery

Pelagic fishery hauls were conducted in Kiel Bight (1 haul), Mecklenburg Bight (3 hauls) Arkona Basin (6 hauls), Bornholm Basin (7 hauls), Stolpe Trench (1 haul), Gotland Basin (3 hauls) and Gdansk Deep (4 hauls) (Table 4.1).

Catches of cod in Mecklenburg Bight, which was sampled for the first time in 2019 on one of our April cruises, stood out in being much higher and characterized by on average larger individuals than in our “standard operating areas” in SD24-26. While own prior data for comparison are lacking, this observation is consistent with findings of collaborators e.g., in March and August in the same area (personal communication Jens-Peter Herrmann, Hamburg University). For SD24-26, catches of cod were higher than for the same time period in 2018. This may in part be explained by improved catchability due to higher oxygen concentrations (see Section 5.3) and resulting higher cod densities near the bottom compared to the more vertically dispersed distribution in 2018. Catches of sprat and flatfishes were higher and of herring somewhat lower than in previous years. It is however important to note that direct quantitative comparisons of catches between years are difficult because the trawls are not standardized. The overall catch composition is shown in Table 5.2.1.

Table 5.2.1 Fish catch composition for AL521. Single fish measurement and samples were taken for 900 cod and 219 whiting individuals. For herring and sprat, sub-samples were taken at each station. For flatfishes and all other species, measurements and fin clips of all individuals were taken.

Latin name	Common name	n	mass (kg)
<i>Sprattus sprattus</i>	sprat	402,136	3,758.5
<i>Clupea harengus</i>	herring	7,721	300.2
<i>Gadus morhua</i>	cod	1,531	604.7
<i>Merlangius merlangus</i>	whiting	667	116.7
<i>Platichthys flesus</i>	flounder	163	30.5
<i>Limanda limanda</i>	common dab	440	75.2
<i>Pleuronectes platessa</i>	plaice	199	41.1
<i>Gasterosteus aculeatus</i>	three-spined stickleback		5.8
<i>Rhinonemus cimbrius</i>	four bearded rockling	2	0.2
Other species		31	8.3
Total		412,890	4,941

For cod, single fish data (length, weight, sex and maturity stage) and samples (otoliths, fin clips for genetic analysis, gonads and livers) were obtained for 900 individuals in total (see Figure 5.2.2 for illustration). Length and weight were measured for an additional 631 individuals. In Bornholm Basin, the main spawning area of Baltic cod, the mean size of individuals had declined to 31.1 cm from 32.9 cm in 2018 (Figure 5.2.1), and larger individuals >45 cm, which were frequently observed in past decades, were mostly absent from the population. Both of these observations are consistent with temporal trends over past years, and represent a dramatic difference from size distributions in the 1980s and 1990s, when much larger individuals were prevalent in the population.

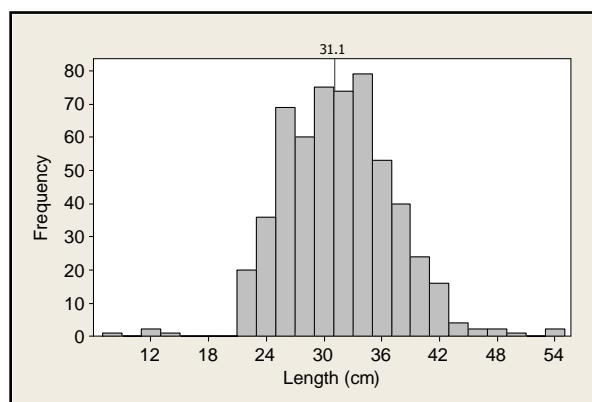

Figure 5.2.1 Length frequency distribution of cod sampled in SD25 during AL521 (n = 561). The mean size of individuals, 31.1 cm, is marked on the x-axis, and compares to 32.9 cm in 2018.

Figure 5.2.2 Samples (otoliths, fin clips, gonads, livers) and measures (total length, weight, gutted weight, liver and gonad weight) were taken from 900 out of 1531 cod individuals (illustrated here for a 38 cm female, maturity stage IV, with full stomach, from Bornholm Basin). Photo: S. Nickel

For sprat and herring, stomach samples (sprat: 20 per 1 cm length class; herring: 20 per 2 cm length class) as well as 2 kg frost samples were taken at each station.

5.3 Hydrography

CTD profiles were obtained with the ADM-CTD (109 stations) and the HYDROBIOS water sampler with attached CTD (14 stations). Two additional vertical oxygen profiles were obtained for calibration purposes at the deep central Bornholm Basin station BB23 and the Gotland Basin station GB79, by determining oxygen concentrations in depth resolved water samples taken with the water sampler using the Winkler method.

Compared to the same time period in 2018, oxygen concentrations in the deeper layers of Bornholm Basin but also Gdansk Deep showed an increase, and the extent of areas with anoxic (0 ml/l) or hypoxic ($< 2 \text{ ml/l}$) conditions at depths below of 70 m and down to the bottom declined. Consequently, the reproductive volume for cod increased. Temperatures above the halocline were in the range of $\sim 6^\circ\text{C}$ compared to $\sim 3^\circ\text{C}$ in the same period in 2018, i.e., clearly higher. In the western Baltic Sea (SD22 - Mecklenburg Bight and the western part of SD24 - Arkona Basin), surface salinities were clearly reduced, around 9 psu vs. 11-15 in previous years, which was likely related to a consistent period of easterly winds that prevailed right up to the start of the cruise, pushing low salinity surface waters from more eastern areas westwards. The combined observations of environmental parameters and the differences compared to the same time period in 2018 once again underscored the strong potential for fluctuations in environmental conditions from year to year on top of any long-term changes that are taking place in the Baltic.

5.4 Food web structure of pelagic systems in the deep basins of the Baltic Sea (Ina Stoltenberg, Jan Dierking, EU Horizon 2020 project GoJelly)

Work during AL521 was a continuation of sampling efforts that took place during the ALKOR cruises AL507 and 509 in April and May 2018 (see the respective cruise reports for details). The project aims to provide better understanding of the role of jellyfish in marine food webs, with a focus on the interactions between jellyfish and commercially important fish species. In GoJelly, the Baltic Sea is as one of several case study areas to address these topics, with other areas including Norwegian Fjords, Madeira in the North Atlantic and the eastern Mediterranean.

During AL521, four stations (KB06 in Kiel Bight, BB15 and 23 in Bornholm Basin, and GB79 in Gotland Basin) were intensively sampled to obtain sample sets for later analyses of fatty acid and stable isotope composition as food web markers. This included jellyfish ephyrae and small medusae, fish adults and larvae, and the main representatives of lower trophic levels (e.g., copepods, cladocerans). Additionally, phytoplankton and water samples were taken for chlorophyll, carbon to nitrogen ratios, bacteria and nutrient measurements. All sampling was carried out as planned, resulting in a total set of 403 samples for food web analysis and additional analyses back in the laboratory on land. Additionally, tissue samples of 294 jellyfish individuals were taken to support genetic analyses of Norwegian GoJelly partners at NTNU.

5.5 Importance of zooplankton species as prey for fish larvae in the Baltic Sea assessed with eDNA analysis (Andreas Novotny, Karen Petersen, Monika Winder, Stockholm University, in collaboration with the Research Unit Marine Evolutionary Ecology at GEOMAR)

This research project based at Stockholm University aims to study ecosystem-wide species interactions in the Baltic Sea. By applying DNA metabarcoding to field collected specimens we want to increase our understanding of each species ecological niche and trophic positioning, and answer the question “who eats whom?”. The main objective during AL521 was to expand our studies beyond plankton-plankton interactions and include larger consumers such as fish larvae and fish. We collected samples from bacteria and phytoplankton communities, micro- and mesozooplankton, fish larvae (sprat and flounder) and adult fish stomachs from sprat, herring and sticklebacks and preserved them for later DNA analysis. Samples were collected in Kiel

Bight (KB06), Arkona Basin (H22), Gotland Basin (BG79), and the Bornholm basin (BB07, BB15, BB23, and BB35). Given the taxonomic and spatial coverage of the sampling, this cruise turned out successful and the objectives were accomplished. As next steps, the diversity of *16S* and *18S rRNA* genes associated with the content of fish stomachs and guts will be analysed on an Illumina MiSeq sequencing platform during summer and fall 2019. We are also developing a quantitative PCR assay to be able to estimate the proportions of copepods, rotifers and cladocerans in the diet of planktivorous fish and fish larvae.

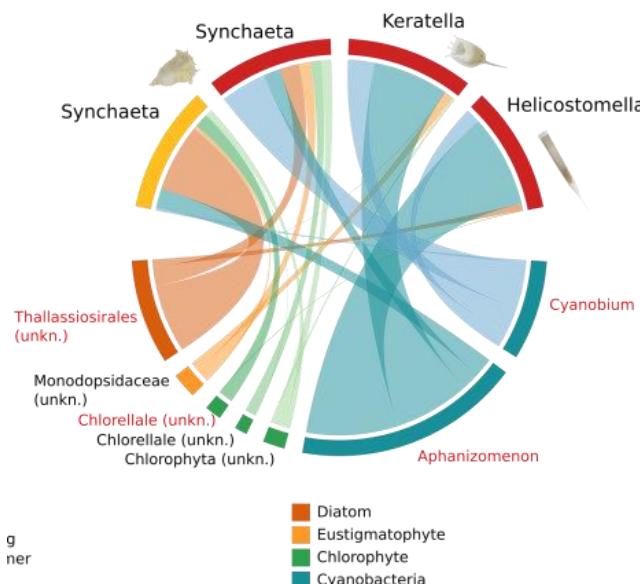

Figure 5.5.1 Output of own previous work (in progress) illustrating the proportion of different food items (lower) associated with different consumers (upper - in this case microzooplankton).

5.6 Marine microbes and viruses of the Baltic Sea under climate change (Luisa Listmann, Elisa Schaum, Hamburg University, in collaboration with the Research Unit Marine Evolutionary Ecology at GEOMAR)

As part of this project on the ecological and evolutionary effects of different temperatures and salinities in the Baltic Sea on phytoplankton, we aim to answer the following questions: a) Does the short-term physiological response of picoplankton to temperature and salinity differ between samples from different regions of the Baltic Sea? b) From which regions of the Baltic Sea can we isolate *Ostreococcus* sp. and its associated viruses?

To help answer these questions, we took surface water samples at 16 stations along the cruise track of AL521. On board, we measured photosynthesis and respiratory activity of two different size fractions ($0.2\text{--}2 \mu\text{m}$ and $0.2\text{--}37.5 \mu\text{m}$) immediately after sampling, and assessed these responses over a gradient of salinity and temperature. Furthermore, water samples of the smaller size fractions were set aside to isolate viruses and picoplankton back in the laboratory at the institute in Hamburg. The 16 stations were divided into Kiel Bay (1 station), Mecklenburg Bay (3 stations), the Arkona Basin (4 stations), the Bornholm Basin (6 stations) and the southern Gotland Basin (1 station).

Preliminary analyses of the temperature curves (see Figure 5.6.1) show that the size fractions differ in their metabolic activity, but also point to differences between different regions along the salinity gradient of the Baltic Sea. In-depth analyses are ongoing, and point toward regional environmental forcing (e.g. comparisons between Bornholm Basin and Kiel Bight) having an impact on par with that of seasonal forcing (e.g. comparisons between spring and summer). Our results suggest that while populations from either region can swiftly adjust their metabolic profiles along gradients of environmental change, the underlying mechanisms differ.

For samples from the Bornholm Basin, rapid species sorting seems to explain most of the responses, whereas samples from Kiel Bight tend to respond to environmental change through sorting within the same species and phenotypic plasticity. In-depth analyses are ongoing. Further, we have had first lysis successes pointing toward the presence of lytic host-virus pairs across the Baltic Sea Basins.

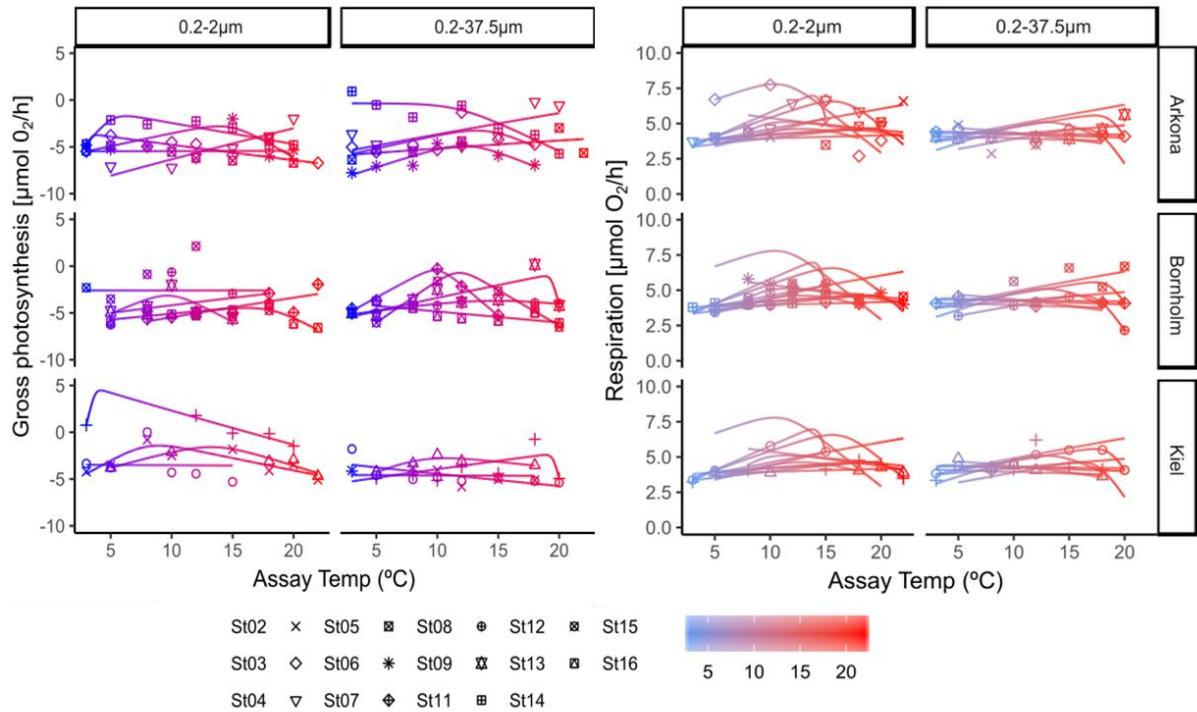

Figure 5.6.1 Temperature reaction norms based on raw data from size fractionated on-board incubations of Kiel Bight, Arkona, and Bornholm samples across a temperature gradient (3°C - 20°C). The left-hand side is for photosynthesis rates in $\mu\text{mol O}_2 \text{ h}^{-1}$, and the right-hand side, for respiration rates in $\mu\text{mol O}_2 \text{ h}^{-1}$. Symbols denote different stations, and the colour gradient the assay temperature (warm – red; cold – blue). Fraction and basin both explain most of the variability found within the temperature profiles. These data were normalized for biomass upon arrival in Hamburg, which changes the intercept, but not the shape of the curves.

6 Station List

In total, 340 gear deployments took place during this cruise (see Table 4.1 for an overview, and Table 6.1 for the full station list). The electronic version of the list and additional cruise data are also permanently available via the GEOMAR OSIS data portal under the link:

<https://portal.geomar.de/metadata/leg/show/348646>.

7 Data and Sample Storage and Availability

All data obtained during the cruise have been backed up on a GEOMAR virtual drive that is backed up daily. In addition, data are stored on different hard drives in different locations. Paper protocols filled out during the cruise were entered electronically continuously throughout the cruise, and thus fall under the electronic back-up scheme, but have also been conserved as hard copies to resolve possible data entry errors later on if needed.

All cruise meta-data – including output of the onboard DSHIP-System – have been entered in the GEOMAR Ocean Science Information System (OSIS), managed by the Kiel Data Management Team (KDMT), and intended for permanent archiving of such data. The data are freely available via the link <https://portal.geomar.de/metadata/leg/show/34864> (keyword “AL521”).

We aim to ultimately make all data accumulated during the cruise publicly available. All hydrographic (CTD) data will be submitted to the ICES database within one year from the cruise. Moreover, the KDMT team will assist with the publication of data in the public data repository PANGAEA to provide long-term archivation and access to the data. Depending on the data set, some of the data are intended for specific publications, and will be published openly with the appearance of the underlying peer-review article. In these cases, please contact the person responsible for the data in case earlier access to the data is desired (Table 7.1).

All samples obtained during the cruise were labelled on board with a barcoding scheme, and all samples intended for longer-term storage were professionally archived immediately after the cruise. This includes formalin conserved samples for long-term storage, and frozen samples (-20°C and -80°C) currently conserved in freezer rooms at GEOMAR.

Table 7.1 Overview of data availability and persons responsible for specific data sets.

Type	Database	Available	Free Access	Contact
Hydrography (CTD data)	ICES database	Publicly by April 2020, earlier on request (see contact e-mail).	By April 2020	jdierking@geomar.de
Fishery data and food web sampling data	PANGAEA	Publicly at time of acceptance of the underlying peer-reviewed publication; alternatively via request (see contact e-mail).		jdierking@geomar.de
Ichthyoplankton data	PANGAEA	See above.		cclemmesen@geomar.de
Hydroacoustic data	PANGAEA	See above.		matthias.schaber@thuenen.de
Phytoplankton community sampling		Inquire with collaboration partner (see contact e-mail).		luisa.listmann@uni-hamburg.de
eDNA sampling		Inquire with collaboration partner (see contact e-mail).		monika.winder@su.se

8 Acknowledgements

I want to thank Captain Helge Volland and the entire crew of RV ALKOR for their outstanding support throughout the cruise and for the excellent and constructive working atmosphere on board. I also thank Svend Mees for his unwavering support, including in all technical matters, Christian Pawlitzki for his support both before and during the cruise, and the scientific personal and student assistants on AL521 for their enthusiasm and motivation.
