Keywords: 2 D multichannel seismic (MCS) reflection data – raw data – GI Gun – GGun array – earthquake – tsunami – Cascadia subduction zone – deformation front – gas hydrates –BSR– carbon-capture & storage (CCS)

Coordinates: *Median Latitude:* 49.36135 * *Median Longitude:* -128.05476 * *South-bound Latitude:* 47.55729 * *West-bound Longitude:* -129.20661 * *North-bound Latitude:* 50.29167 * *East-bound Longitude:* -126.30441

Abstract

The raw 2D multichannel seismic reflection data in this project were acquired during expedition SO294 offshore Vancouver Island, Canada, using two different sources, i.e., a single GI Gun and a GGun array. The data were recorded with an 184-channel streamer. The objectives of expedition SO294 were twofold: provision of geophysical images to constrain the hazard potential of the Cascadia subduction zone, and to constrain the geophysical properties of the oceanic crust to assess its storage potential for carbon capture and storage (CCS). The data comprise 1660 line kilometers and are provided in raw format (SEG-D) and associated standardized metadata. Detailed information on the acquisition can be found in the SO294 cruise report (https://doi.org/10.48433/cr_so294). In addition, this technical report is provided with the 2D multichannel seismic reflection data set.

1 Introduction

Expedition SO294 served two scientific projects. The main part of the cruise was concerned with the project CLOCKS: “Northern Cascadia: Extent of locked zone, prism deformation, slip-to-toe, and the edge of subduction”. The Cascadia subduction zone extending from northern California to the northern tip of Vancouver Island, remains unbroken by a megathrust earthquake since January 26, 1700, which is known from tsunami records in Japan. Based on previous studies, the megathrust fault on the subducting Juan de Fuca (JdF) Plate is believed to be fully locked. Along a 2D profile from the deformation front to the shelf off Vancouver

Island, marine MT data were recorded for one month. A landward extension of the profile across Vancouver Island was recorded by the University of Alberta. We acquired seismic data across the deformation front at the central northern Cascadia margin to image faulting and identify potential slip-to-throw events where the megathrust may have ruptured out to the deformation front. Seismic data were also collected in the Winona Basin (Explorer Plate) to address the extent of subduction off northern Vancouver Island. All seismic shots were co-recorded on Ocean-Bottom-Seismographs (OBS) to allow P-wave and S-wave velocity analysis.

The second project is a collaborative study between GEOMAR and Ocean Networks Canada (ONC) on potential CO₂ storage in marine basalt complexes called CASCADIA CO₂ (CCO₂). The project aims to study the lateral variability of the basalt formations and their physical properties by acquiring seismic data on OBS optimized for the measurement of S-waves - a dataset yet missing in the assessments of the CO₂ storage potential of basalt.

2 Seismic Acquisition

During SO294, several types of long-term monitoring instruments were deployed on the central accretionary prism: nine short-period long-term OBS (JAMSTEC), six OBP (Kobe Univ., Tokyo Univ., JAMSTEC), and six broad-band long-term OBS (GEOMAR). An additional eleven short-period long-term OBS (JAMSTEC) were deployed north of the Nootka Fault in the Winona Basin region. These instruments will be recovered during expeditions led by the GSC in 2023 (OBS, Douglas et al., 2024) and 2024 (OBP).

A total of 54 short-term OBS used for active-source seismic refraction analyses were used in three sub-regions of the study area: 22 OBS were deployed along two perpendicular profiles in the Cascadia Basin with the CCO₂ project, 20 OBS were used along two parallel profiles in the Winona Basin, and 12 OBS were used in one profile across the central accretionary prism off Vancouver Island.

The seismic refraction experiments were carried out with a six GGun array with a combined volume of 2840 in³ (84 L) and a total of 370 km of profile length was acquired across the OBS. An additional 180 km were acquired on cross-lines not directly above the 2D OBS profiles. High-resolution seismic reflection imaging was achieved using a single GI airgun (355 in³, 6 L) and a MCS streamer consisting of 184 channels at 1.56 m spacing over a 290 m total active length. Reflection data were acquired in the Winona Basin (685 km) and across the deformation front of the central accretionary prism off Vancouver Island (425 km).

During SO294, a total of 1660 km of 2D multichannel seismic (MCS) reflection data were acquired, forming an extensive grid of lines in each of the three research areas (Figure 3). The goal was to image the subsurface with a focus on the oceanic crust. In total, we shot seven surveys with two different acquisition geometries. P1000 (Figure 4) was part of the secondary user project CCO₂. Surveys P2000, P3000, and P7000 were part of OBS refraction

measurements, while P4000, P5000, and P6000 were dedicated to high-resolution streamer seismic acquisition. A list of lines acquired for each setup can be found in *6 Acknowledgments*.

2.1 Streamer Set-up

We used 23 active streamer sections each consisting of eight channels at a spacing of 1.5625 m (Geometrics GeoEel streamer segments, 12.5 m). This resulted in 287.5 m of active streamer length. In Figures 1 and 2, the streamer set-up, deck geometries, and gun settings for the 2D surveys are visualized. The receiver system consisted of a 40 m-long tow cable (from the stern of the vessel), a 20 m-long stretch section, followed by 23 active streamer sections (7 oil-filled, 16 solid-state) and another stretch section, to reduce the drag noise of the tail-buoy at the end of the streamer. The active sections were connected with analog-to-digital (AD) converter modules, which communicated with the recording system in the lab via a TCP/IP protocol. A repeater connected the deck cable and the tow cable (lead-in). In the lab, the streamer power supply unit constituted the connection between the recording system and the AD modules. It also handled the management of the streamer power supply.

For maintaining a constant streamer depth of 2 m (4 m for P7000), four bird Remote Units (RUs) were attached to the streamer during the survey. The birds communicated with the controller via coils embedded in the streamer and the information was transmitted via a twisted pair of wires within the deck cable. Two RUs were directly attached to the stretch and the 5th active section. The other two were attached to 1.56 m long bird sections added to the streamer between the active sections 13/14 and 19/20. The bird sections did not contain hydrophones. As a consequence, the total length of the streamer is 290.6 m.

The seismic data were A/D converted within digitizing bottles within each streamer segment and transferred to the ship using an ethernet network. The data were recorded with an SPSU and Geometrics software in SEG-D format.

For navigation, we mounted a GPS antenna on the ship's superstructure close to the stern of the vessel. The position of this GPS antenna was measured with a tape measure and related to the towing points of the airgun source and the streamer. The navigation data were logged in parallel to the seismic data.

2.2 Seismic Sources

2.2.1 GI Gun

For the high-resolution MCS surveys P4000, P5000, and P6000 (Figure 1), a single GI Gun was used as the seismic source. It was attached to a stringer by two steel chains of about 1 m in length. The set-up was stabilized in a water depth of ~2 m by a large float, attached to the stringer. The gun was operated in Harmonic 355 mode (250 in³ generator and 105 in³ injector chamber) with a pressure of 140 bar. The injector pulse was triggered with a delay of 63 milliseconds after the generator. The shot interval was 10 seconds, equivalent to ~25 m shot point distance at a survey speed of ~4 kn.

2.2.2 GGun Array

The GGun array used during SO294 (Figure 2) consisted of six (6) G Guns operated at a pressure of 140 bar. Two G Guns each formed a cluster, and three clusters were towed together at a distance of 2.5 m from each other. The total length of the array is 8 m. Cluster 1 and 3 consisted of two 520 in³ guns, and the middle cluster comprised two 380 in³ guns. The total volume was 2840 in³ (~ 46 L). The port-side deployment rail was used to deploy the array from the stern of the vessel. During data acquisition, the array was towed 49 m behind the ship's stern at 8 m depth. To achieve sufficient ray coverage while avoiding previous shot noise and allow receivers on land stations to record the signals, the GGun array was used with a shot interval of 60 s, translating to a shot point distance of 150 m at 4 kn speed.

A detailed description of the streamer and source setup can be found in *8 Appendix*.

3 Data Description

The complete raw 2D multichannel reflection seismic data set has been archived at the German repository PANGAEA. The data have been quality controlled before archiving. However, for completeness, all recorded shots, whether qualified or not, have been included in the archiving process.

In addition, the seismic watchkeeping log called *SO294_2D_Seismic_watchkeeping_log.xls* documents any changes or problems during the acquisition and logging of the data. The navigation files listed in Table 2 have been attached and linked to the data set.

Please note that the line numbering in this technical report has been revised after the first quality control and might differ from the original final line numbering referred to in the original logs and final report linked to this data set.

4 Data Quality/ Accuracy

The seismic data are of good quality and do not show significant noise apart from a bubble pulse and the seafloor multiple. Due to the relatively soft seafloor both these noise sources do not affect the imaging in a significant way. Still, it will be useful to suppress the seafloor multiple with more sophisticated processing as the data show clear evidence of primary reflections below the onset of the first seafloor multiple, especially in shallow water <1500 m water depth. The penetration of the seismic data is generally good reaching more than 1 s two-way travel time in parts of the survey area.

However, some interruptions occurred during the data acquisition for various reasons, e.g., spotting marine mammals, troubleshooting regarding the acquisition, weather downtime, etc. Any problems regarding metadata identified during quality control after the survey have been listed for each setup individually in a spreadsheet in the appendix.

Please note that these lists do not cover all shot points recorded and archived. Only shot points identified to have an issue are included.

Table 3: Abbreviation

ntbp	not to be processed (Please note: This just might be a suggestion even if there exists a SEG-D file due to major acquisition problems!)
SP	Shot Point
FSP	First Shot Point
FGSP	First Good Shot Point
LSP	Last Shot Point
LGSP	Last Good Shot Point
NMEA	NMEA 0183 is a combined electrical and data specification for communication between marine electronics such as echo sounders, sonars, anemometers, gyrocompass, autopilot, GPS receivers, and many other types of instruments. It has been defined and is controlled by the National Marine Electronics Association (NMEA). This standard provides different versions depending on the setup of the recording systems. However, they all fulfill the requirements of GPS positioning and time. In case, the string has been "not recorded", necessary metadata like positioning can be obtained via DShip.

5 Data Availability/ Access

The raw seismic files and all corresponding logs and spreadsheets or files have been archived at PANGAEA <https://doi.pangaea.de/10.1594/PANGAEA.961490>

The data will be freely available after the end of the moratorium period of four years ending 27th October 2027, unless the author has applied for an extension. When using the data, please cite this data publication. Recommended citation is:

Riedel, M., Bialas, J., Klein, E., Berndt, J., 2024. 2D multichannel seismic reflection raw data (GI Gun & GGun array entire dataset) of RV SONNE during cruise SO294. PANGAEA, <https://doi.pangaea.de/10.1594/PANGAEA.961490>

6 Acknowledgments

We acknowledge the Nuu-Chah-Nulth Tribal Council (NTC) and their member Nations as well as the Quatsino and Pacheedaht Nations on whose marine traditional territories we conducted our science.

The Federal Ministry of Education and Research (BMBF) funded the project under grants 03G0294A (CLOCKS) and 03G0294B (CASCADIA) with extra funding and the use of large-scale equipment from GEOMAR.

Further additional funding has been provided through the Japan Society for the Promotion of Science (JSPS), Japan Agency for Marine-Earth Science and Technology (JAMSTEC), University of Tokyo, Kobe University, Geological Survey of Canada (Public Safety Geoscience Program), Ocean Networks Canada, and the University of Alberta for the land MT-Program.

Figure 19: Streamer setup for P7000

Cruise SO294_CLOCKS
 Line: P7000

Date: 14.10.2022

shot mode: G-Gun
 shot rate: 30 sec
 delay: 55 ms
 pressure: 140 bar

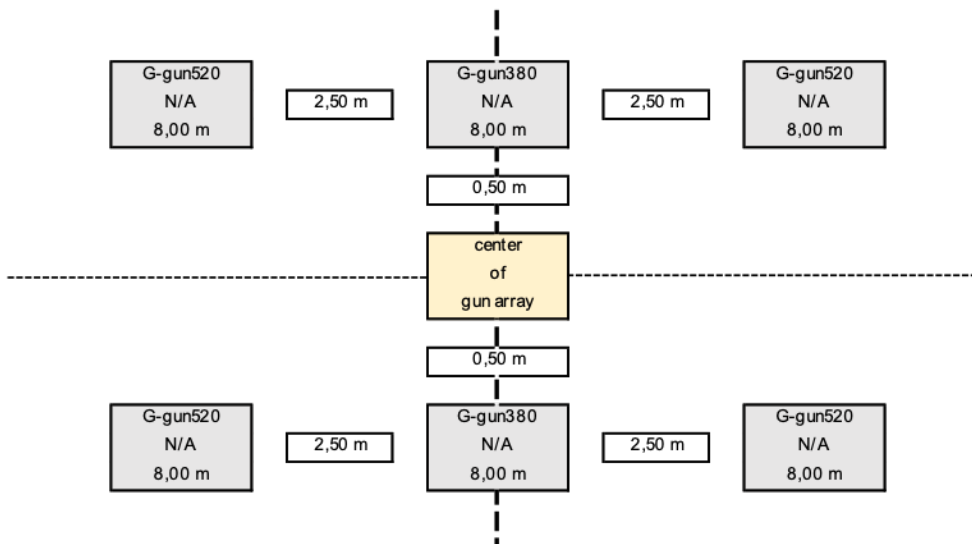

Figure 20: Source setup for P7000
